

Online Computation of Fastest Path in Time-Dependent Spatial Networks

Instructor: Cyrus Shahabi

Cost of Traffic Congestion

Traffic congestion is a **\$121 billion annual drain** on the U.S. economy¹:

- 5.5 billion lost hours
- 2.9 billion gallons of wasted fuel
- Travelers had to allow for 60 minutes to make a trip that takes 20 minutes in light traffic.

¹ Texas Transportation Institute Urban Mobility Report, 2012 data

A screenshot of a news article from TIME magazine. The headline reads: "Location data could save consumers worldwide more than \$600 billion annually by 2020." Below the headline, a large quote discusses the consumer benefits of location-based services. The article is framed by a purple border, and the TIME website navigation bar is visible at the top.

Location data could save consumers worldwide more than \$600 billion annually by 2020.

The biggest single consumer benefit will be from time and fuel savings from location-based services — tapping into real-time traffic and weather data — that help drivers avoid congestion and suggest alternative routes.

Intelligent Transportation

PROBLEM

- Traffic congestion is a **\$87.2 billion annual drain** on the U.S. economy¹:
 - 4.2 billion lost hours (one work week for every traveler)¹
 - 2.8 billion gallons of wasted fuel (three weeks worth of gas for every traveler)¹
- ¹ Texas Transportation Institute Urban Mobility Report, 2007 data

GOAL

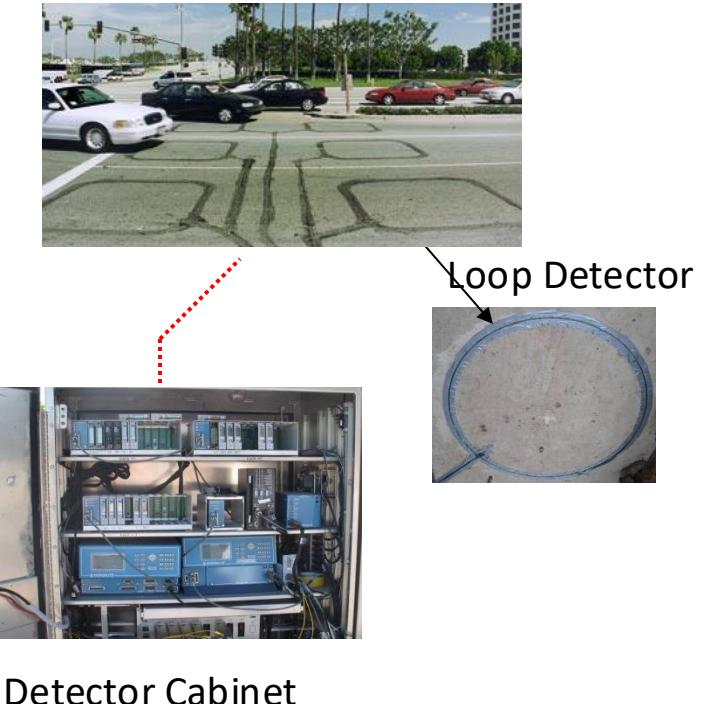

- To improve the performance of the surface transportation network through:
 - Capturing real-time data from infrastructure and vehicles
 - Developing data-driven solutions to improve mobility by leveraging optimization opportunities (e.g., path planning for commuter groups)

Traffic Data Lifecycle

- **Loop Detectors**

- Most commonly used traffic sensors
- The data is collected in Detector Cabinet and relayed to the service provider
- Provide two data fields: volume (count) and occupancy (% time a vehicle is over the sensor)

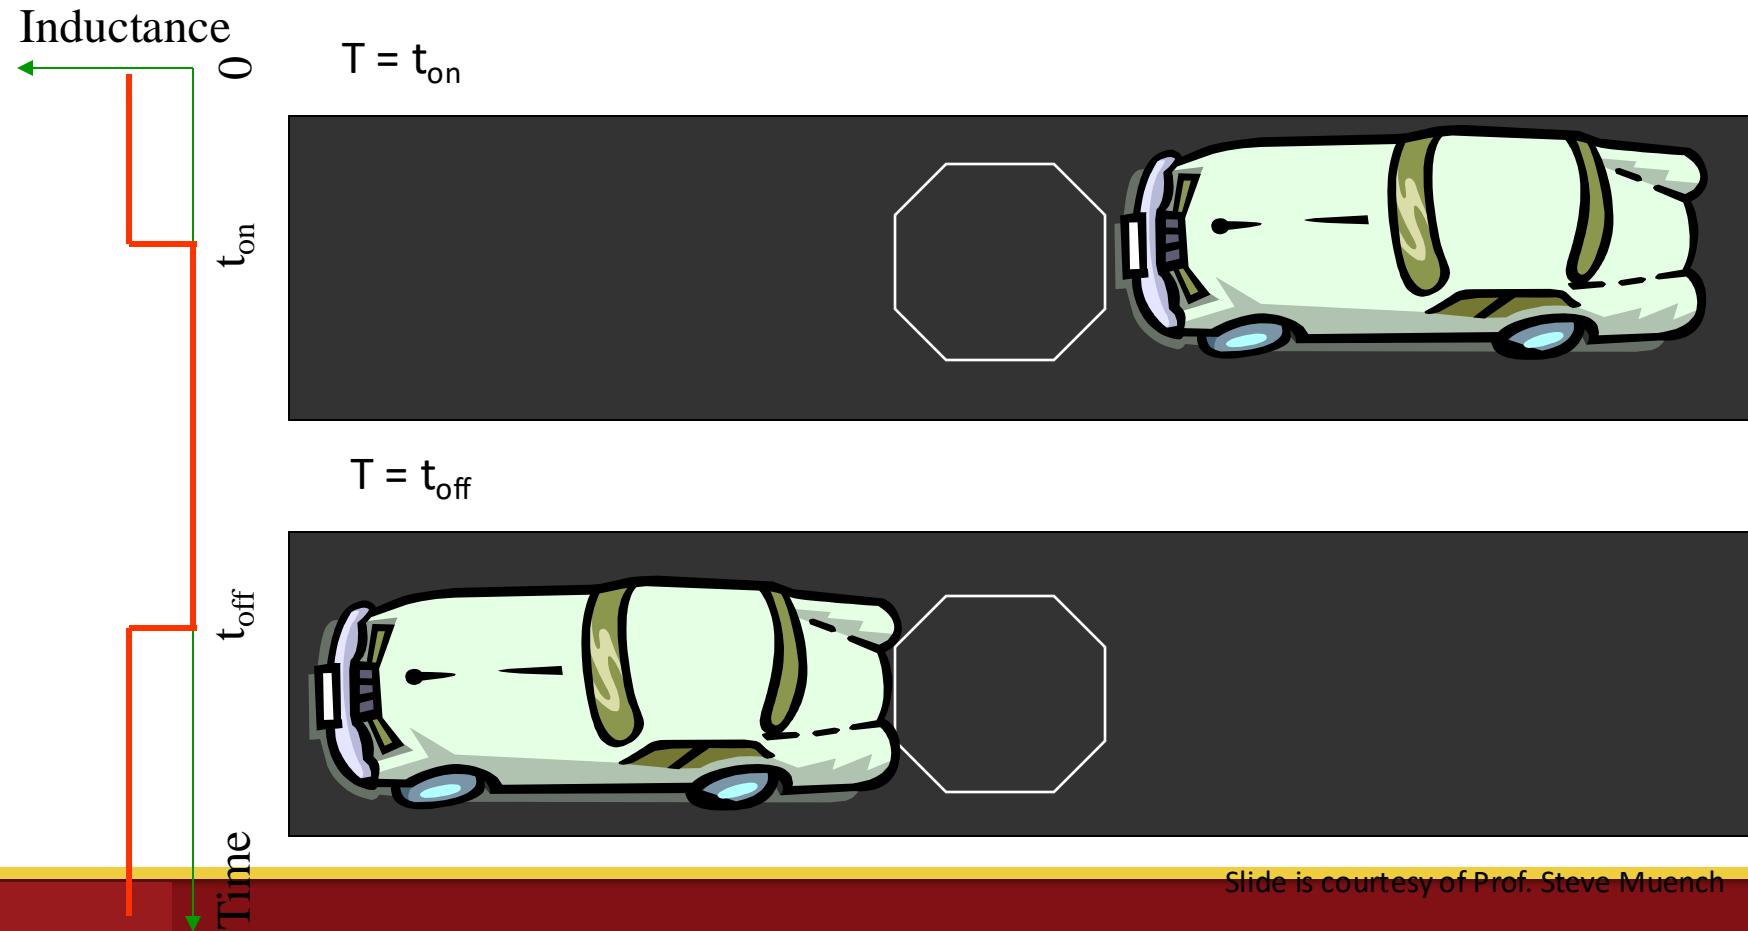

Detector Cabinet

Traffic Data Lifecycle: Loop Detectors

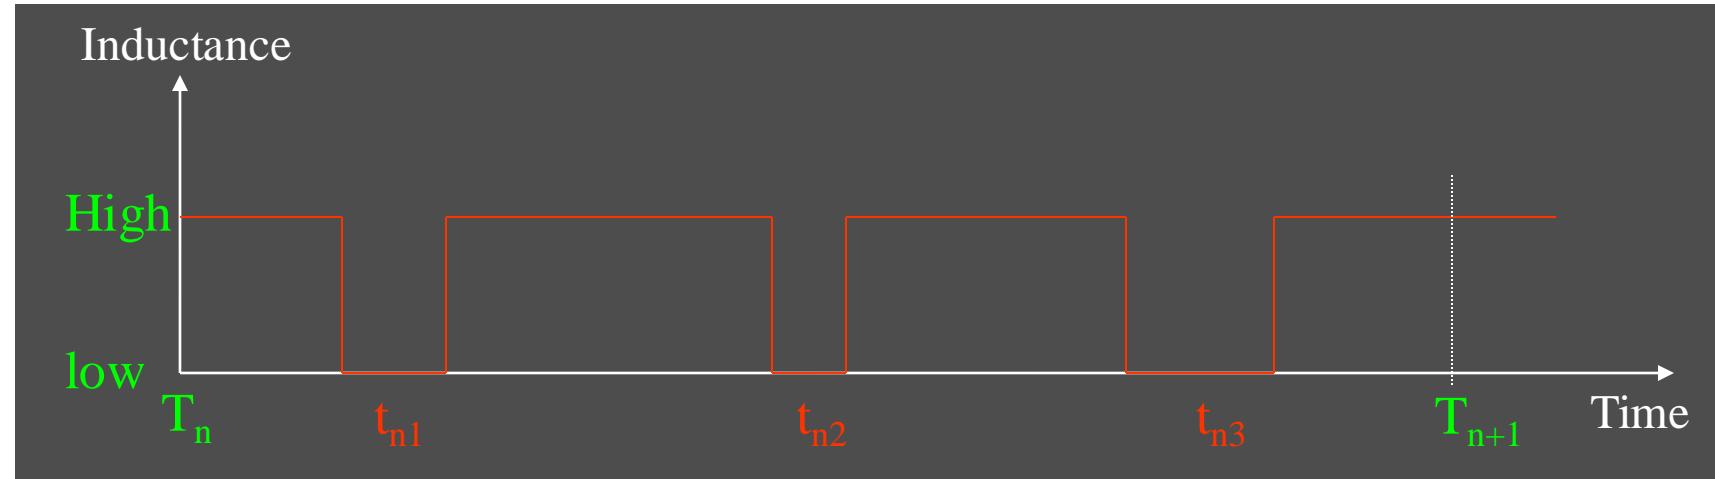

Loop inductance decreases when a car is on top of it.

Slide is courtesy of Prof. Steve Muench

Traffic Data Lifecycle: Loop Detectors

- **Single loops can measure:**
 - **Occupancy (O):** % of time loop is occupied (had a car on it) per interval
 - **Volume (N):** vehicles per interval
 - **Speed = $(N*L)/O$** where L is a constant proportional to the average length of a car

Slide is courtesy of Prof. Steve Muench

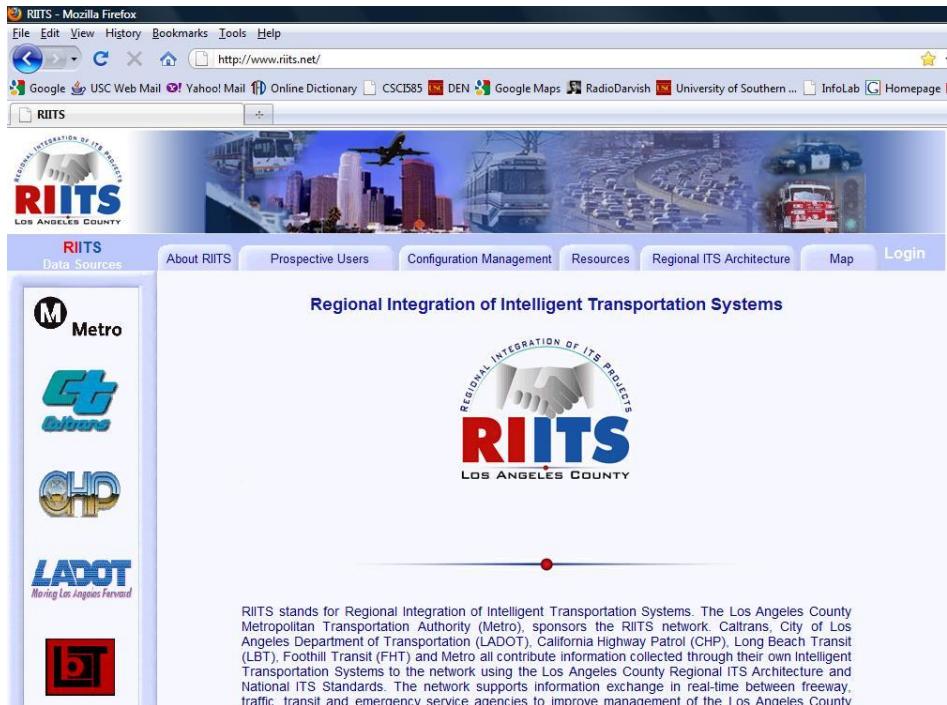

Traffic Data Lifecycle: Data Aggregator

RIITS (Regional Integration of Intelligent Transportation Systems)

- A data network affiliated with Los Angeles County Metropolitan Transportation Authority (Metro)
- Collects and serves data from Caltrans, City of Los Angeles Department of Transportation (LADOT), California Highway Patrol (CHP), Long Beach Transit (LBT), Foothill Transit (FHT) and Metro

<http://www.riits.net/>

The screenshot shows the RIITS website homepage. At the top, there's a banner with a collage of transportation-related images including a bus, a train, a car, and an airplane. Below the banner is a navigation bar with links for "About RIITS", "Prospective Users", "Configuration Management", "Resources", "Regional ITS Architecture", "Map", and "Login". To the left, there's a sidebar titled "RIITS Data Sources" featuring logos for "Metro", "LBT", "CHP", "LADOT", and "FHT". In the center, there's a large RIITS logo with the text "REGIONAL INTEGRATION OF ITS PROJECTS" around the top and "RIITS LOS ANGELES COUNTY" below it. At the bottom, there's a detailed description of what RIITS stands for and its purpose.

RIITS stands for Regional Integration of Intelligent Transportation Systems. The Los Angeles County Metropolitan Transportation Authority (Metro) sponsors the RIITS network. Caltrans, City of Los Angeles Department of Transportation (LADOT), California Highway Patrol (CHP), Long Beach Transit (LBT), Foothill Transit (FHT) and Metro all contribute information collected through their own Intelligent Transportation Systems to the network using the Los Angeles County Regional ITS Architecture and National ITS Standards. The network supports information exchange in real-time between freeway, traffic, transit and emergency service agencies to improve management of the Los Angeles County.

REVISED
PLANNING AND PROGRAMMING
APRIL 14, 2010

SUBJECT: CONTRACT NO. PS 4340-2301, ARCHIVE DATA MANAGEMENT SYSTEM (ADMS)

ACTION: AWARD A 3-YEAR FIRM FIXED PRICE CONTRACT TO METRANS TRANSPORTATION CENTER OF UNIVERSITY OF SOUTHERN CALIFORNIA

RECOMMENDATION

Authorize the Chief Executive Officer (CEO) to award a 3-year firm fixed price contract, Contract No. PS 4340-2301, ADMS, to University of Southern California (USC) for Professional Services in an amount not to exceed \$1,799,210, effective May 3, 2010.

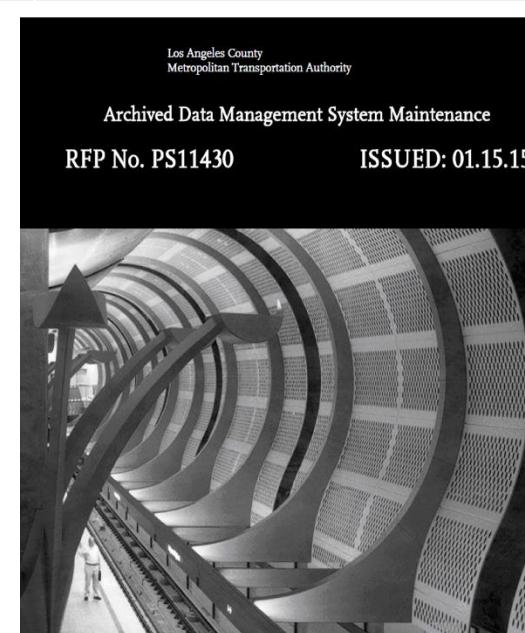

RATIONALE

Over the last four years, the Regional Integration of Intelligent Transportation System (RIITS) network and program has been expanding to develop new interfaces with additional cities and transportation agencies such as Foothill Transit, Los Angeles Department of Transportation (LADOT)/Metro Rapid Bus, Los Angeles County Department of Public Works, California Highway Patrol, and Caltrans Districts 8 and 12. In addition, RIITS continues to be the primary source of real-time traffic congestion data for Los Angeles County 511, Information Service Providers (ISPs), and third party data users for distribution of congestion data under separate formats for public consumption.

Distance Computation

Time-Dependent Spatial Network (2003-2010)
Spatial Network (2010-)

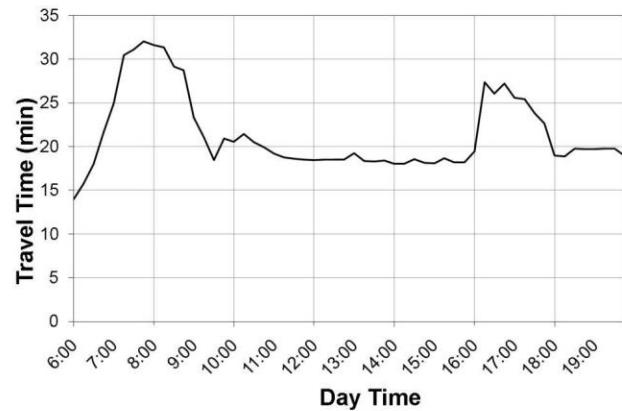

Edge weight change over time

Problem Definition

- Given a time-dependent spatial network where edge weights are function of time

Source s and Destination d

Time-dependent Fastest Path (TDFP)

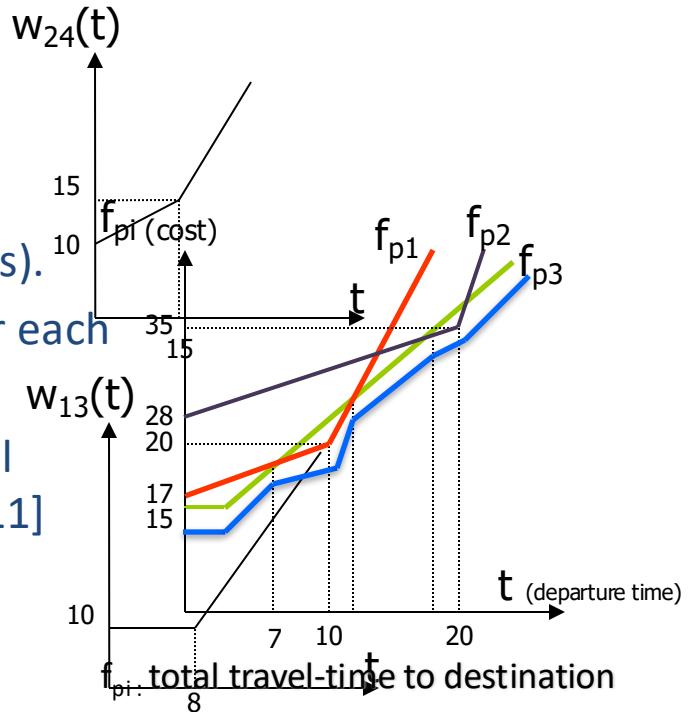

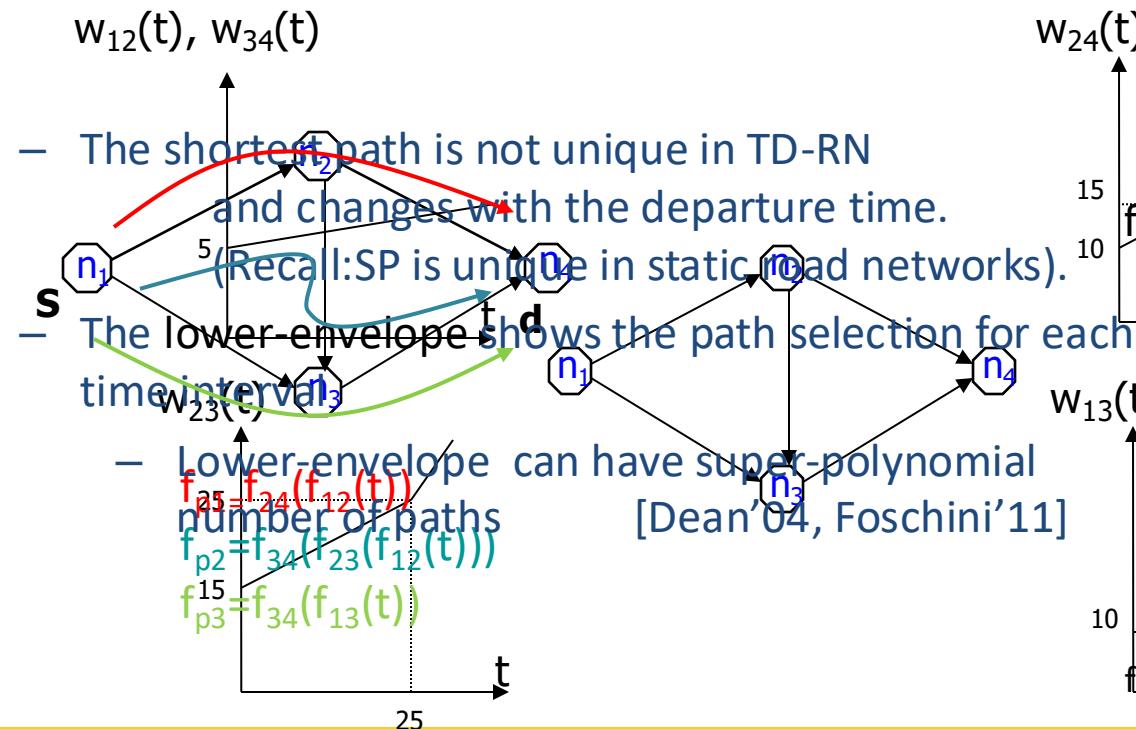

TDFP (s, d, t_s) with respect to s, d and query time t_s finds *minimum travel time path* among all paths between s and d

Challenge: Too big of a graph to find optimal path in real-time
Typical Approach, Pre-computation, doesn't work

Challenges

- Is Pre-computation feasible?
 - Compute and store all distance values between all pairs of nodes

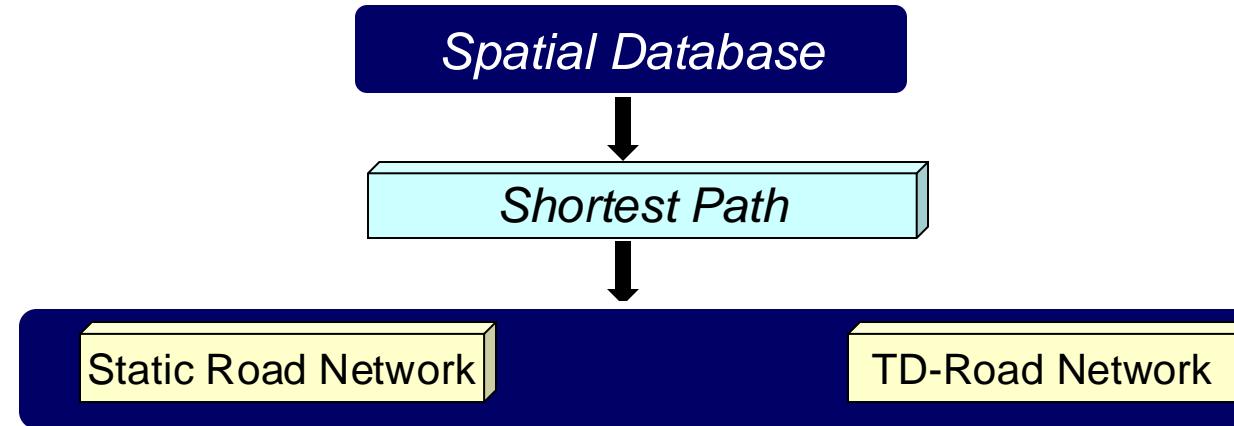

Outline

- Distance Computation
- Motivation
- Related Work
- Time-dependent A* Search
- Experimental Evaluation

Preliminaries: Static Network

- Dijkstra vs. A*

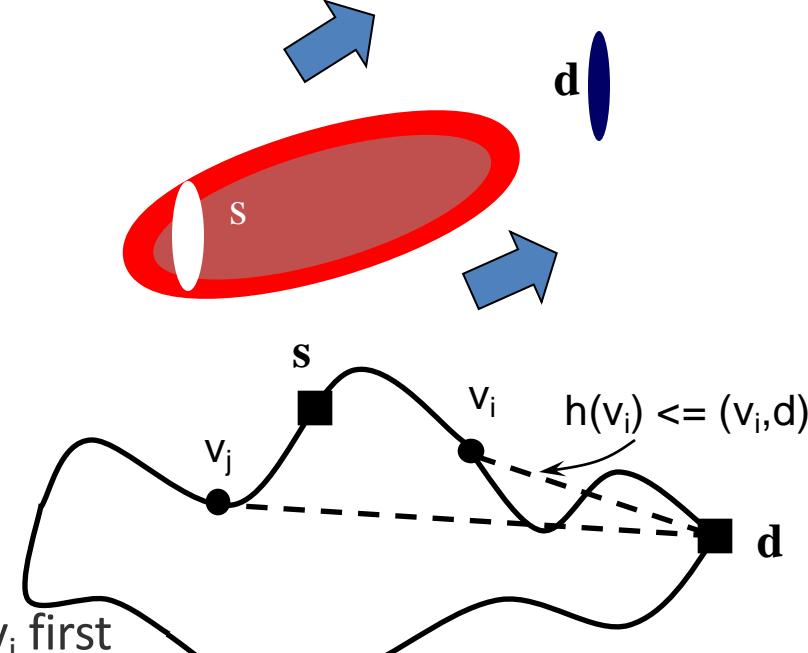

Problem: 48% of network nodes are scanned

Dijkstra: since $(S, v_j) < (S, v_i)$, expand v_j first

A*: since $(s, v_i) + h(v_i) < (s, v_j) + h(v_j)$, expand v_i first

Optimality Condition: $h(v_i)$ should not overestimate the actual distance between v_i and d .

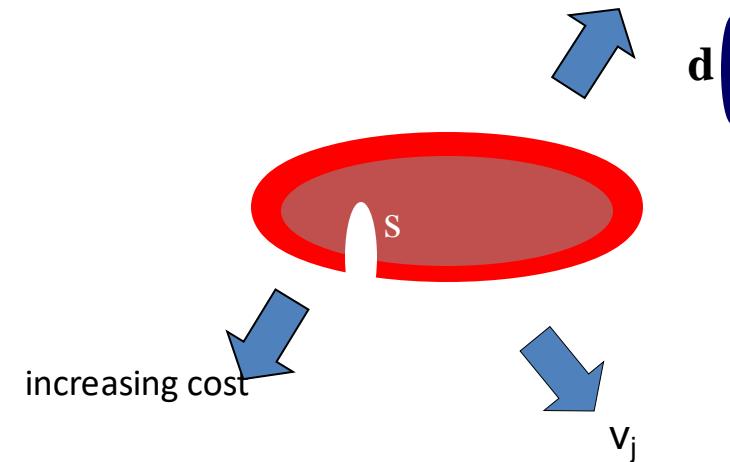

A* Algorithm

Preliminaries: Time-Dependent Network

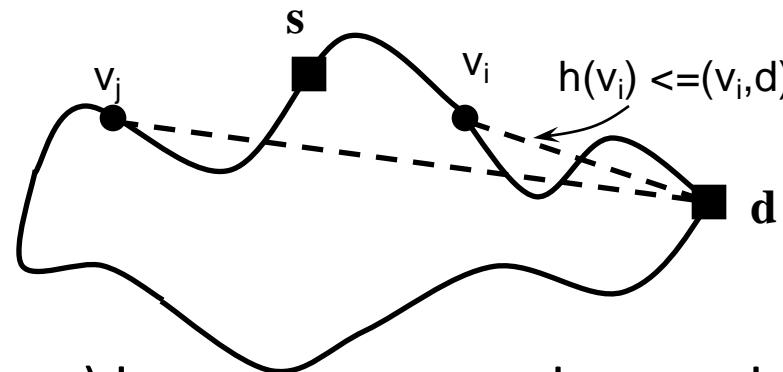

- The time-dependent shortest path problem can be solved by modifying Dijkstra Algorithm **[Dreyfus'69]**
 - **Greedy Algorithm:** Starting from s , the network nodes reachable from s in every direction are visited in order of their ***arrival-time***

Time-dependent A* Search

- **Challenge:** Finding heuristic function $h(v_i, d) \leq D(v_i, d, t)$ in TD Networks

- The distance (travel-time) between any node v_i and d changes in Time-dependent Road Networks
- $h(v_i, d)$ also needs to be time-dependent

Time-dependent A* Search (Naïve Approach)

- **Naïve Heuristic Function:**

$$\frac{D_{EUC}(v_i, d)}{\max(\text{speed})}$$

Euclidean distance between v and d divided by the maximum speed among the edges

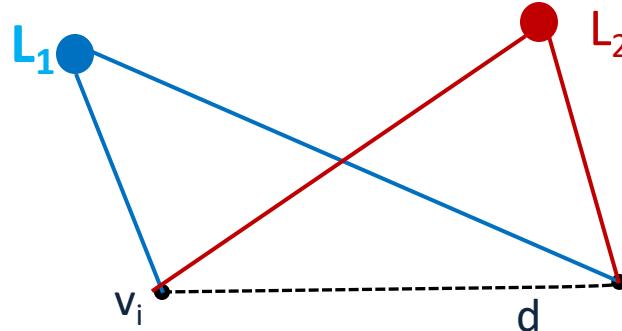

- **Guaranteed** to be a lower-bound as the distance between v and d is never overestimated
- **Problem:** It is a very **loose bound**, hence yields insignificant performance improvement

Chabini & Shan [Trans ITS'02]

Time-dependent A* Search

- **ALT-A* with Landmark and Triangular Inequality:** Originally proposed to accelerate fastest path computation in static road networks [WEA'09]

- Landmark selection is difficult and relies on assumptions
- The size of the search space is severely affected by the location of landmarks [Potamias'09]
$$h(v,d) = \max\{\text{dist}(L_1,v) - \text{dist}(L_1,d), (\text{dist}(L_2,v) - \text{dist}(L_2,d))\}$$
- So far no optimal strategy (NP-Hard) with respect to landmark selection and random queries has been found [Potamias'09]
- Space inefficient: need to store precomputed distances from each node to each landmark

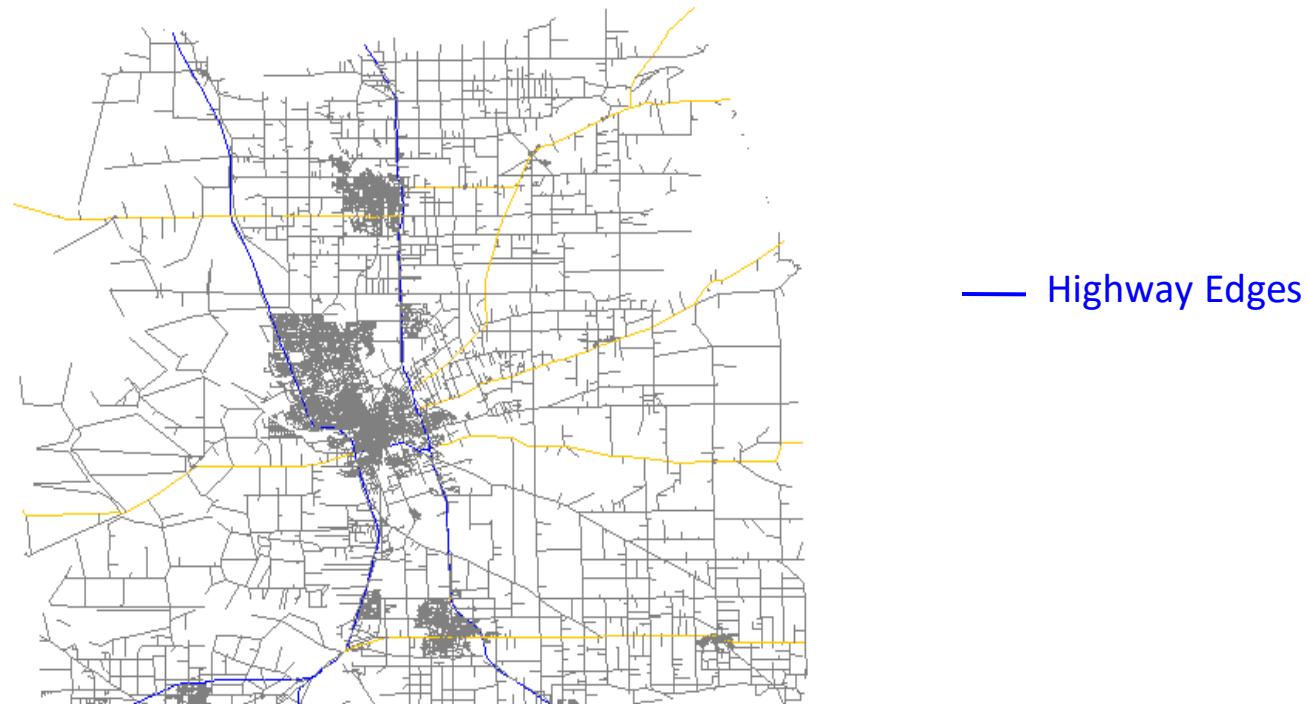

Time-dependent A* Search

- Goal:
 - Find a $h(v_i)$ that will **never overestimate** the time-dependent travel-time between v_i and d . This is necessary for **Exact** results
 - $h(v_i)$ should be as **close as possible to actual** distances for **Efficient** processing of fastest path computation
- Approach:
 - **Step 1:** Partition the road network into non-overlapping partitions (**Offline**)
 - **Step 2:** Precompute $h(v_i)$ using distances in and between the non-overlapping partitions (**Offline**)

Time-dependent A* Search (Our Approach)

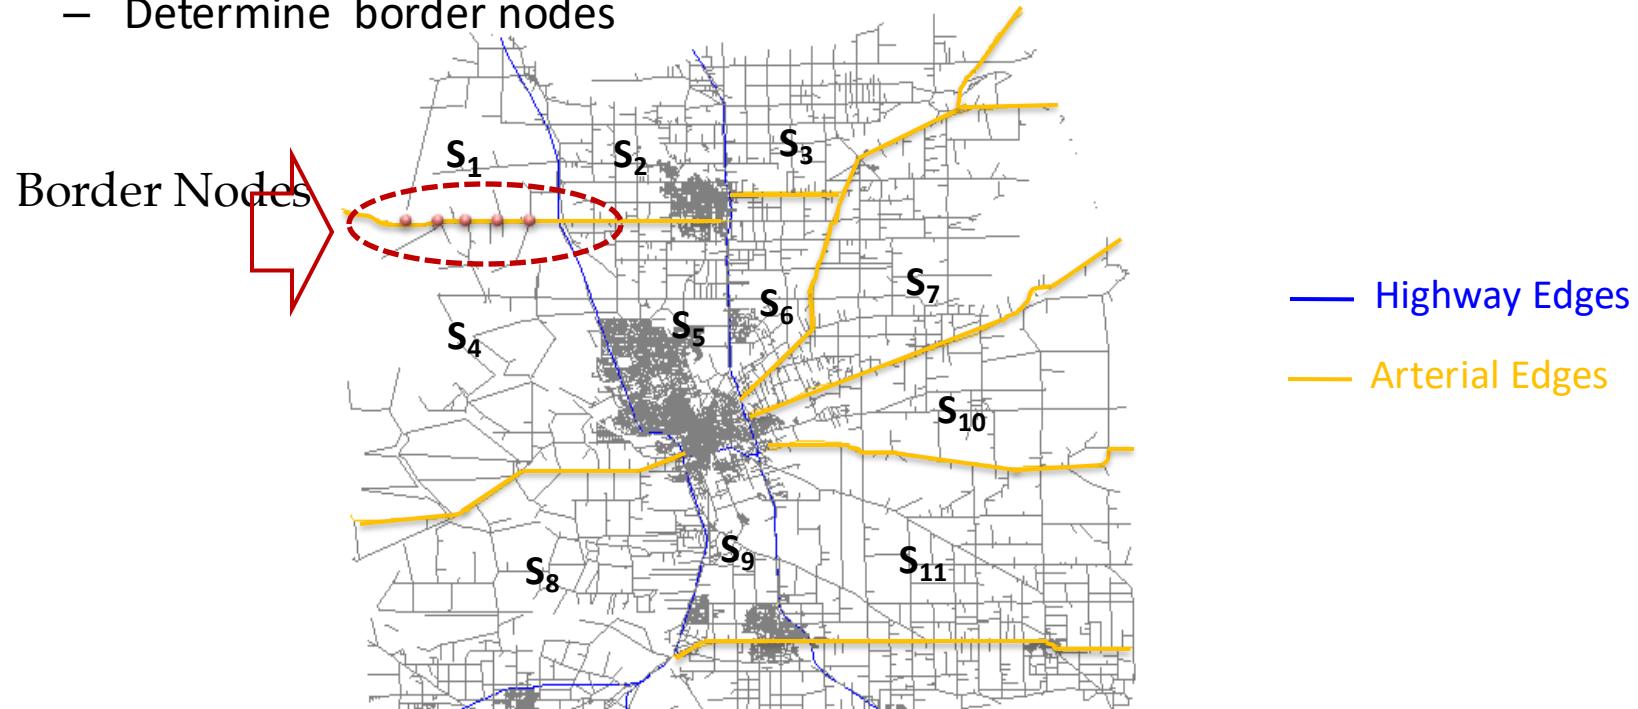

- **Step 1: Partition** the road network using network hierarchies
 - Partition the road network to highways (highest level)

Time-dependent A* Search

- **Step 1: Partition** the road network using network hierarchies
 - Partition the road network using highest level roads (i.e., highways)
 - Partition each partition using lower level road network (i.e., arterials)
 - Determine border nodes

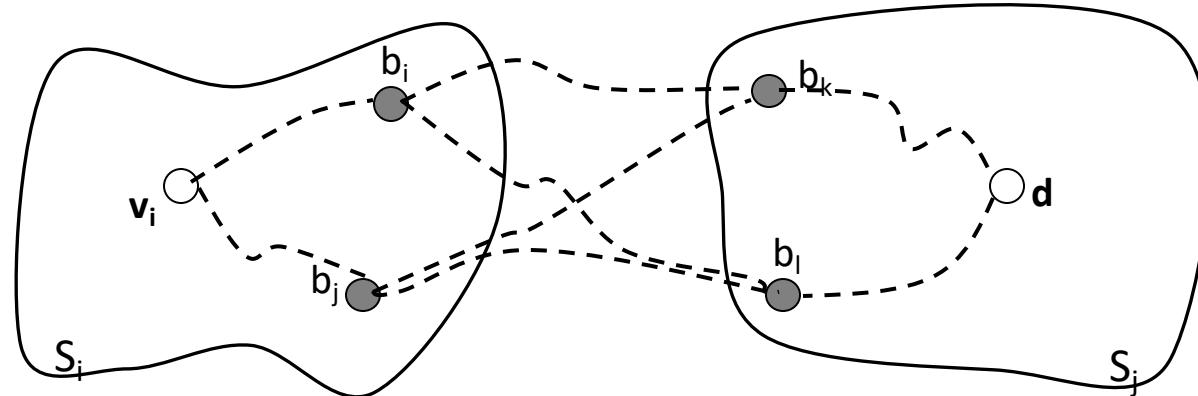

Our algorithm yields correct results with all non-overlapping partitioning algorithms

Time-dependent A* Search

- **Step 2: Compute intra and inter distance labels**
 - **Intra:** fastest path in [Lower-bound Graph G](#) (where edge weights are travel-time, i.e., fastest speed) from each node v_i to border nodes and border nodes to v_i
 - **Inter:** fastest path in [Lower-bound Graph G](#) between border nodes

- Only store the minimum of node-to-border, border-to-border, and border-to-node travel times

$$LTT(v_i, b_i) = \arg \min(LTT(v_i, b_i), LTT(v_i, b_j))$$

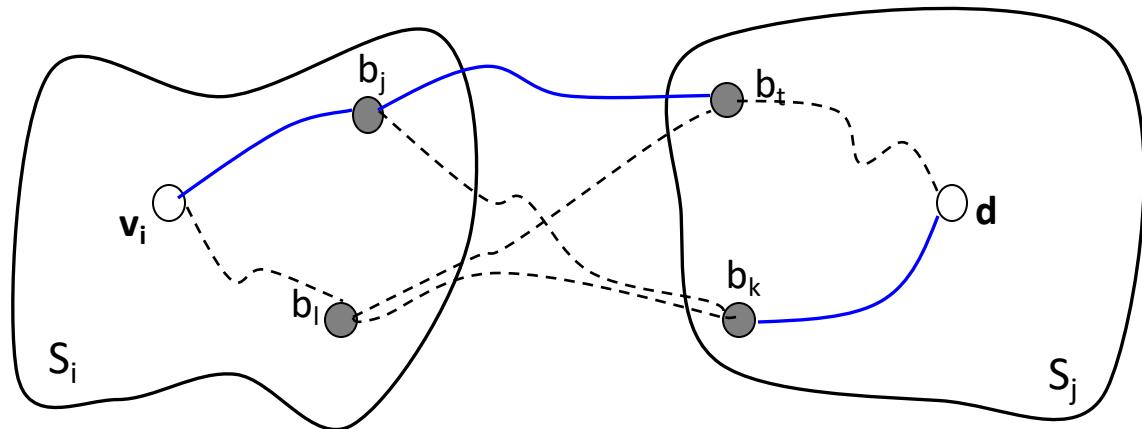

$$LTT(b_l, d) = \arg \min(LTT(b_k, d), LTT(b_l, d))$$

$$LTT(b_i, b_k) = \arg \min(LTT(b_i, b_k), LTT(b_i, b_l), LTT(b_j, b_k), LTT(b_j, b_l))$$

Time-dependent A* Search

- **Lemma:** $h(v_i, d)$ based on intra and inter distance labels is lower-bound of $\text{TDFP}(v_i, d, t)$:

- **Proof:** $h(v_i, d) \leq \text{TDFP}(v_i, d, t_{vi})$
 $LTT(v_i, b_i) \leq \text{TDFP}(v_i, b_i, t_{vi}), LTT(b_i, b_t) \leq \text{TDFP}(b_i, b_t, t_{bi}),$
 $LTT(b_k, d) \leq \text{TDFP}(b_k, d, t_{bk})$
$$h(v_i, d) = LTT(v_i, b_i) + LTT(b_i, b_t) + LTT(b_k, d) \leq \text{TDFP}(v_i, d, t_{vi})$$

Time-dependent A* Search

- **Low Storage Overhead**

- Only partition, node-to-border and border-to-node information is added to each node v_i
- Border-to-border information is a small fraction of the all network

Node	Partition	Node-to-Border	Border-to-Node
n_1	S_1	$b_1, 5$	$b_1, 7$
n_2	S_1	$b_2, 6$	$b_3, 4$
....
n_{41}	S_9	$b_{17}, 3$	$b_{15}, 6$
n_n	S_k	b_u, x	b_v, y

Node-to-Border (Intra)

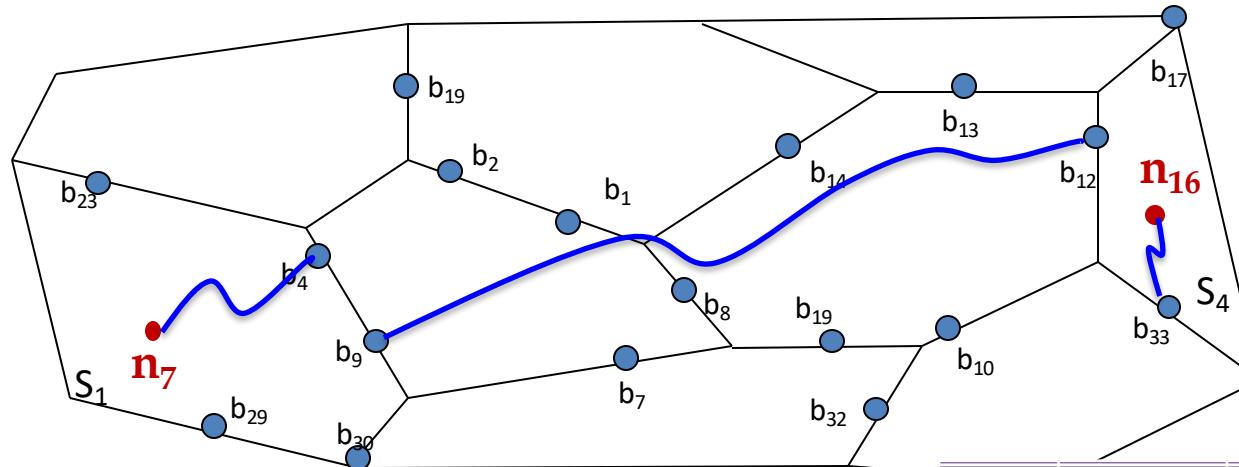

Border	Border	Distance	Partition
b_1	b_3	14	S_1, S_4
b_1	b_{41}	18	S_1, S_3
b_1	b_{15}	12	S_4, S_1
....
b_n	b_k

Border-to-Border (Inter)

Time-dependent A* Search

- Fast $h(v_i, d)$ computation
 - $h(v_i, d)$ is computed by simple table look-ups (nanoseconds)

Node	Partition	Node-to-Border	Border-to-Node
n ₆	S ₁	b ₂₃ ,5	b ₂₃ ,7
n ₇	S ₁	b ₄ ,6	b ₉ ,4
....
n ₁₆	S ₄	b ₁₇ ,3	b ₃₃ ,5
n _n	S _k	b _u ,x	b _v ,y

- Efficient updates $h(n_7, d) = 6+18+5$
 - Distance labels are only updated if lower-bound distances changed

Time-dependent A* Search

- Can we further improve the performance of unidirectional TD A* search?

Bidirectional Time-dependent A* Search

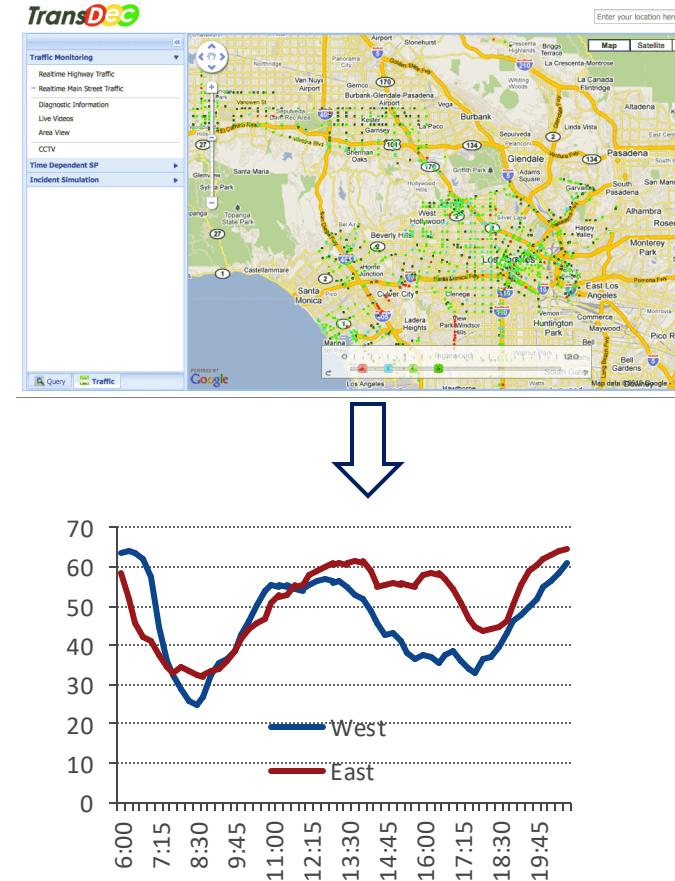

Outline

- Distance Computation
- Motivation
- Related Work
- Time-dependent A* Search
- Experimental Evaluation

Experimental Evaluation

- **Road Network Dataset
(obtained from Navteq)**
 - Los Angeles (LA) Network with 304,162 nodes
 - California (CA) Network with 1,965,300 nodes
- **Time-dependent Network Data
(obtained from ADMS)**
 - LA Metro, Price School of Public Policy and IMSC
 - 6500 Sensors on freeways and arterials in LA
 - 1 sensor/reading per minute
 - Collecting and archiving past 2 years
- **Experimental Setup:**
 - A server with 2.7 GHz Pent. Duo Core Proc. and 12GB RAM
 - Source, destination and departure time t_s are determined uniformly at random
 - Average results computed from 1000 random s-d queries

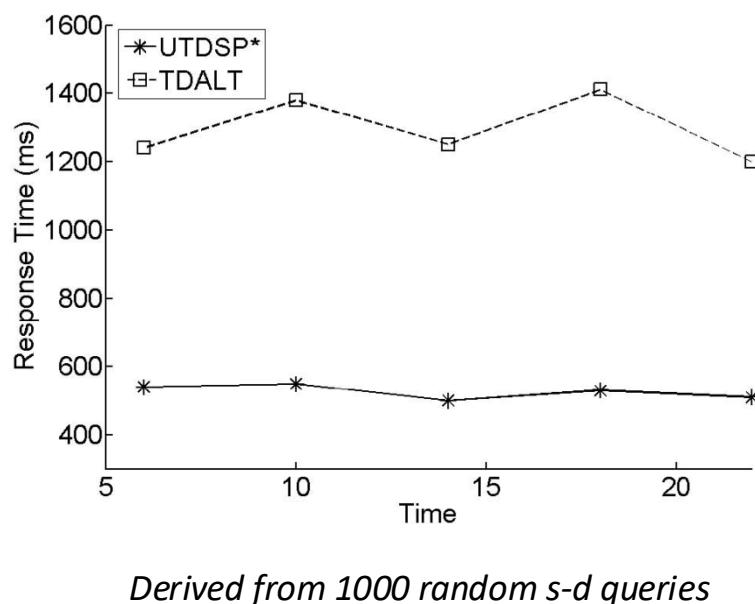

Experimental Evaluation

- **Comparison with TD-ALT**

- TD-ALT: Determine 64 landmarks based on maxCover (best known landmark selection algorithm)
- TDFP: Divide CA network to 64 partitions

Response Time:

- TD-ALT very loose bounds based on the randomly selected s and d , and hence the large search space.

Storage:

- TD-ALT attaches each node an array of 64 elements. Total Storage = 63 MB for CA
- TDFP attaches each node an array of 2 elements (intra distance labels) and b-to-b. Total Storage=8.5 MB for CA

L.A. Expo Line hasn't reduced congestion, a study finds

USC researchers found that the 8.6-mile Expo Line did accomplish a worthy goal: boosting transit ridership in a dense, car-choked corridor. (Irfan Khan / Los Angeles Times)

By Dan Weikel and Alice Walton · Contact Reporters

NOVEMBER 17, 2015, 4:00 AM

Contrary to predictions used to promote the first phase of the Expo light rail line between downtown and Los Angeles' Westside, a new study has found that the \$930-million project has done little to relieve traffic congestion in the area.

Crosstown Foundry Newsletter

- Markdown Template
- Edit static and dynamic newsletter content
- Mixins (dynamic content)
- Grammar:
NAME:AGGREGATION:FILTERS
 - JavaScript modules encoding data or data visualizations queried from the Crosstown Databases
 - Localized to specific spatial and temporal extent
- HTML Converter & Linter
- Validates mixins
- Renders the markdown in HTML

Newsletter March 2, 2021

Name
covid, vaccines, arrests, plumbing

Description

```
### Happy March, 'READER'

This is Lauren Whaley, writing from East Hollywood. Here is your weekly Crosstown Neighborhood Newsletter for CURRENT_WEEK on life in NEIGHBORHOOD. This week, we look at infections, vaccinations, arrests and plumbing permits.
```

<i>Do you have 15 minutes for a Zoom call to give us feedback about our newsletter? We'll thank you with a \$5 Starbucks gift card. Sign up here.</i>

<hr>

```
### COVID-19 infections slow, but so do vaccinations
```

'NEIGHBORHOOD' infections

Feb. 22 - 28: COVID_INFECTIONS::20210221,20210228 new COVID-19 infections
